cycloids-package	<i>Calculating coordinate representations of hypocycloids, epicycloids, hypotrochoids, and epitrochoids</i>
------------------	---

Description

Functions for calculating coordinate representations of hypocycloids, epicycloids, hypotrochoids, and epitrochoids (altogether called 'cycloids' here) with different scaling and positioning options. The cycloids can be visualised with any appropriate graphics function in R.

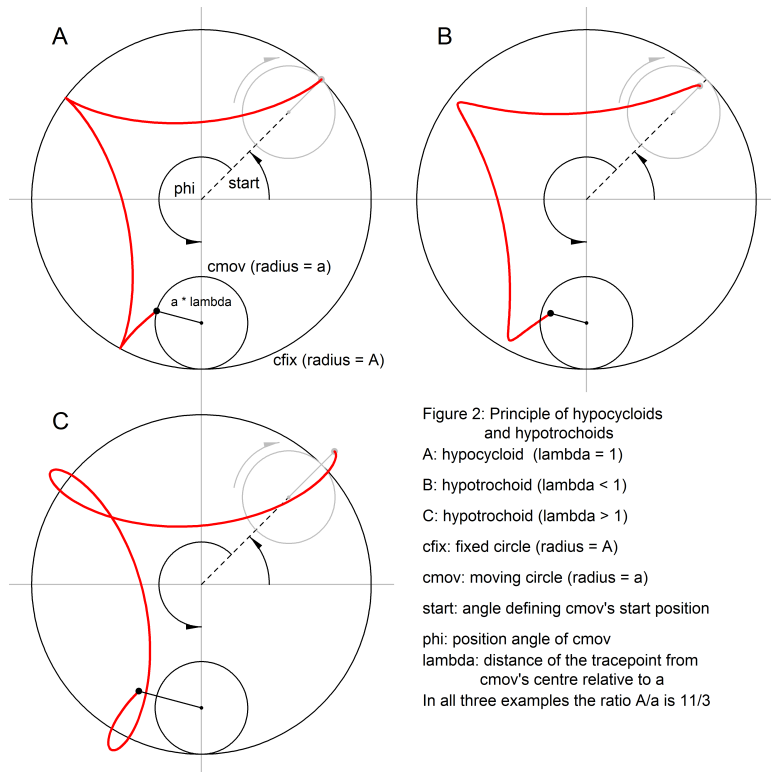

Details

This package has been written for calculating cartesian coordinate representations of hypocycloids, epicycloids, hypotrochoids, and epitrochoids (altogether called 'cycloids' here). These can be easily visualized with any R graphic routine that handles two-dimensional data. All examples shown here use standard R graphics. While there are technical applications, the main purpose of this package is to create mathematical artwork.

Geometrically, cycloids in the sense of this package are generated as follows (Figure 1, 2): Imagine a circle *cfix*, with radius A , which is fixed on a plane. Another circle, *cmov*, with radius a , is rolling along *cfix*'s circumference at the outside of *cfix*. The figure created by the trace of a point on *cmov*'s circumference is called an epicycloid (Figure 1A). If *cmov* is rolling not at the outside but at the inside of *cfix*, the trace of a point on *cmov*'s circumference is called a hypocycloid (Figure 2A).

If in both cases the tracepoint is not located on *cmov*'s circumference but at a fixed distance from its midpoint either in- or outside *cmov*, the resulting figure is an epitrochoid (Figure 1B, C) or a hypotrochoid (Figure 2B, C), respectively. Hypotrochoids and epitrochoids became quite popular through toys like the spirograph.

The most important functions of the package are [zykloid](#), [zykloid.scaleA](#), [zykloid.scaleAa](#), and [zykloid.scaleP](#).

Note

Type `demo(cycloids)` for seeing some examples.

ggT

Calculates the greatest common divisor of two natural numbers a and b based on the Euclidean Algorithm

Description

The function ggT calculates the greatest common divisor of two natural numbers. In this package it is called by the function kgV which calculates the least common multiple of two natural numbers.

The latter is needed by the function `zykloid` and by the function `npeaks` which calculates the number of peaks (or loops) a cycloid has. As the greatest common divisor might be useful for other purposes, the function `ggT` is accessible to external use in this package.

Usage

```
ggT(a, b)
```

Arguments

<code>a</code>	A natural number (integer value > 0)
<code>b</code>	A natural number (integer value > 0)

Value

A natural number if *a* and *b* are natural numbers. In any other case, the function returns NA.

ggT(3.2, 12)    # NA - only integer numbers > 0 allowed
```

kgV

*Calculates the least common multiple of two natural numbers a and b***Description**

The function `kgV` calculates the least common multiple of two natural numbers. In this package it is used by the function `zykloid` and by the function `npeaks` which calculates the number of peaks (or loops) a cycloid has. As it might be useful for other purposes, it is externally available in this package.

Usage

```
kgV(a, b)
```

Arguments

<code>a</code>	A natural number (integer value > 0)
<code>b</code>	A natural number (integer value > 0)

Value

A natural number if a and b are natural numbers. In any other case, the function returns NA.

```
npeaks           Calculates the number of a cycloid's peaks based on the radii A (fixed
                  circle) and a (moving circle)
```

Description

This function may be useful for calculating the number n of peaks a cycloid ([zykloid](#)) based on the radii A (fixed circle) and a (moving circle) will have. The equation for n is

$$n = \text{kgV}(A, a) / a$$

where $\text{kgV}(A, a)$ is the least common multiple of A and a as implemented in the function [kgV](#)

Usage

```
npeaks(A, a)
```

Arguments

```
A           A natural number (integer value > 0)
a           A natural number (integer value > 0)
```

Value

A natural number if A and a are natural numbers. In any other case, the function returns NA.

zykloid	<i>Core function for calculating coordinate representations of hypocycloids, epicycloids, hypotrochoids, and epitrochoids (altogether called 'cycloids' here)</i>
---------	---

Description

This is the package's core function for calculating cycloids. These are represented by a set of two-dimensional point coordinates. Although this function provides the essential mathematics, you may want to use the wrappers `zykloid.scaleA`, `zykloid.scaleAa`, and `zykloid.scaleP` due to their convenient scaling and positioning options.

Usage

```
zykloid(A, a, lambda, hypo = TRUE, steps = 360, start = pi/2)
```

Arguments

A	The Radius of the fixed circle <i>cfix</i> . Must be an integer Number > 0.
a	The radius of the moving circle <i>cmov</i> . Must be an integer Number > 0. Together with A, a determines the resulting cycloid's shape and number of peaks which can be calculated with <code>npeaks</code> .
lambda	The distance of the tracepoint from the moving circle's (<i>cmov</i>) centre in relative units of its radius a. <i>lambda</i> = 1 means that the tracepoint is located on <i>cmov</i> 's circumference. For <i>lambda</i> < 1, the tracepoint is on <i>cmov</i> 's area, e.g. if <i>lambda</i> = 0.5, it is halfway between <i>cmov</i> 's centre and its circumference. If <i>lambda</i> > 1 the tracepoint is outside <i>cmov</i> 's area, you might imagine it being attached to a rod which is attached to <i>cmov</i> and crosses its centre. E.g. <i>lambda</i> = 2 would mean that the tracepoint's distance from <i>cmov</i> 's centre equals 2 * a. <i>lambda</i> = 0 produces a circle because the tracepoint is identical with <i>cmov</i> 's centre.
hypo	logical. If TRUE, the resulting figure is a hypocycloid (<i>lambda</i> = 1) or a hypotrochoid (<i>lambda</i> ! = 1), because <i>cmov</i> is rolling along the inner side of the fixed circle (<i>cfix</i>). If FALSE, an epicycloid (<i>lambda</i> = 1) or an epitrochoid <i>lambda</i> ! = 1 is generated, as <i>cmov</i> is rolling at the outside of <i>cfix</i> 's circumference.
steps	positive integer. The number of steps per circuit of the moving circle (<i>cmov</i>) for which tracepoint positions are calculated. The default, 360, means steps of 1 degree for the movement of <i>cmov</i> . Analogously, steps = 720 would mean steps of 0.5 degrees.
start	Start angle (radians) of the moving circle's (<i>cmov</i>) centre counterclockwise to the horizontal with the fixed circle's (<i>cfix</i>) centre as the pivot. The tracepoint will start at a peak.

Details

Geometrically, cycloids in the sense of this package are generated as follows (Figure 1, 2): Imagine a circle *cfix*, with radius *A*, which is fixed on a plane. Another circle, *cmov*, with radius *a*, is rolling along *cfix*'s circumference at the outside of *cfix*. The figure created by the trace of a point on *cmov*'s circumference is called an epicycloid (Figure 1A). If *cmov* is rolling not at the outside but at the inside of *cfix*, the trace of a point on *cmov*'s circumference is called an hypocycloid (Figure 2A).

If in both cases the tracepoint is not located on *cmov*'s circumference but at a fixed distance from its midpoint either in- or outside *cmov*, the resulting figure is an epitrochoid (Figure 1B, C) or a hypotrochoid (Figure 2B, C), respectively.

With the arguments of *zykloid* as defined above, the centre of *cfix* in the origin, and *phi* being the counterclockwise angle of *cmov*'s midpoint against the start position with *cfix*' centre as the pivot, the cartesian coordinates of a point on the cycloid are calculated as follows:

$$x = (A + a) * \cos(phi + start) - lambda * a * \cos((A + a)/a * phi + start)$$

$$y = (A + a) * \sin(phi + start) - lambda * a * \sin((A + a)/a * phi + start)$$

Value

A dataframe with the columns *x* and *y*. Each row represents a tracepoint position. The positions are ordered along the trace with the last and the first point being identical in order to warrant a closed figure when plotting the data.

zykloid.scaleA *Wrapper for [zykloid](#) which allows to scale and position a cycloid by the radius A of the fixed circle and its midpoint*

Description

While [zykloid](#) provides the basic functionality for calculating cycloids, this functions allows to re-size a cycloid by freely setting the radius on the fixed circle. In addition, the cycloid can be re-positioned by locating the fix circle's midpoint. See Figures 1 and 2 and [zykloid](#) for the geometrical principles of cycloids.

Usage

```
zykloid.scaleA(A, a, lambda, hypo = TRUE, Cx = 0, Cy = 0,
              RadiusA = 1, steps = 360, start = pi/2)
```

Arguments

A	The Radius of the fixed circle before re-sizing. Must be an integer Number > 0. Together with <i>a</i> (see below), <i>A</i> is only determining the cycloid's shape and number of peaks (see npeaks), while its actual size is defined by the argument <i>RadiusA</i> (see below).
a	The radius of the moving circle before re-sizing. Must be an integer Number > 0. Together with <i>A</i> , <i>a</i> only determines the cycloid's shape and number of peaks (see npeaks), while its actual size is defined via the argument <i>RadiusA</i> (see below).
lambda	The distance of the tracepoint from the moving circle's (<i>cmov</i>) centre in relative units of its radius <i>a</i> . <i>lambda</i> = 1 means that the tracepoint is located on <i>cmov</i> 's circumference. For <i>lambda</i> < 1, the tracepoint is on <i>cmov</i> 's area, e.g. if <i>lambda</i> = 0.5, it is halfway between <i>cmov</i> 's centre and its circumference. If <i>lambda</i> > 1 the tracepoint is outside <i>cmov</i> 's area, you might imagine it being attached to a rod which is attached to <i>cmov</i> and originates from its centre. E.g. <i>lambda</i> = 2 would mean that the tracepoint's distance from <i>cmov</i> 's centre equals 2 * <i>a</i> . <i>lambda</i> = 0 produces a circle because the tracepoint is identical with <i>cmov</i> 's centre.
hypo	logical. If TRUE, the resulting figure is a hypocycloid (<i>lambda</i> = 1) or a hypotrochoid (<i>lambda</i> ! = 1), because <i>cmov</i> is rolling along the inner side of the fixed circle (<i>cfix</i>). If FALSE, an epicycloid (<i>lambda</i> = 1) or an epitrochoid <i>lambda</i> ! = 1 is generated, as <i>cmov</i> is rolling at the outside of <i>cfix</i> 's circumference.
Cx	x-coordinate of the fixed circle's midpoint. Default is 0.
Cy	y-coordinate of the fixed circle's midpoint. Default is 0.
RadiusA	The actual radius of the fixed circle. Default is 1.
steps	positive integer. The number of steps per circuit of the moving circle (<i>cmov</i>) for which tracepoint positions are calculated. The default, 360, means steps of 1 degree for the movement of <i>cmov</i> . Analogously, steps = 720 would mean steps of 0.5 degrees.

start Start angle (radians) of the moving circle's (*mov*) centre counterclockwise to the horizontal with the fixed circle's (*fix*) centre as the pivot. The tracepoint will start at a peak.

Details

Value

A dataframe with the columns *x* and *y*. Each row represents a tracepoint position. The positions are ordered along the trace with the last and the first point being identical in order to warrant a closed figure when plotting the data.

zykloid.scaleAa	<i>Wrapper for zykloid which scales a cycloid by its outer radius and allows free positioning</i>
-----------------	---

Description

While [zykloid](#) provides the basic functionality for calculating cycloids, this functions allows to re-size a cycloid by freely setting the radius of its circumcircle. In addition, the cycloid can be re-positioned by locating the fixed circle's midpoint. This function behaves similarly as [zykloid.scaleP](#). See details. Figures 1 and 2 and [zykloid](#) describe the geometrical principles of cycloids.

Usage

```

zykloid.scaleAa(A, a, lambda, hypo = TRUE, Cx = 0, Cy = 0,
  RadiusAa = 1, steps = 360, start = pi/2)

```

Arguments

- | | |
|--------|--|
| A | The Radius of the fixed circle before re-sizing. Must be an integer Number > 0. Together with <i>a</i> (see below), <i>A</i> is only determining the cycloid's shape and number of peaks (see npeaks), while its actual size is defined by the argument <i>RadiusAa</i> (see below). |
| a | The radius of the moving circle before re-sizing. Must be an integer Number > 0. Together with <i>A</i> , <i>a</i> only determines the cycloid's shape and number of peaks (see npeaks), while its actual size is defined via the argument <i>RadiusAa</i> (see below). |
| lambda | The distance of the tracepoint from the moving circle's (<i>cmov</i>) centre in relative units of its radius <i>a</i> . <i>lambda</i> = 1 means that the tracepoint is located on <i>cmov</i> 's circumference. For <i>lambda</i> < 1, the tracepoint is on <i>cmov</i> 's area, e.g. if <i>lambda</i> = 0.5, it is halfway between <i>cmov</i> 's centre and its circumference. If <i>lambda</i> > 1 the tracepoint is outside <i>cmov</i> 's area, you might imagine it being attached to a rod which is attached to <i>cmov</i> and crosses its centre. E.g. <i>lambda</i> = 2 would mean that the tracepoint's distance from <i>cmov</i> 's centre equals 2 * <i>a</i> . <i>lambda</i> = 0 produces a circle because the tracepoint is identical with <i>cmov</i> 's centre. |

hypo	logical. If TRUE, the resulting figure is a hypocycloid ($\lambda = 1$) or a hypotrochoid ($\lambda \neq 1$), because <i>cmov</i> is rolling along the inner side of the fixed circle (<i>cfix</i>). If FALSE, an epicycloid ($\lambda = 1$) or an epitrochoid ($\lambda \neq 1$) is generated, as <i>cmov</i> is rolling at the outside of <i>cfix</i> 's circumference.
Cx	x-coordinate of the fixed circle's midpoint. Default is 0.
Cy	y-coordinate of the fixed circle's midpoint. Default is 0.
RadiusAa	The actual radius of the cycloids outer circle. Default is 1.
steps	positive integer. The number of steps per circuit of the moving circle (<i>cmov</i>) for which tracepoint positions are calculated. The default, 360, means steps of 1 degree for the movement of <i>cmov</i> . Analogously, steps = 720 would mean steps of 0.5 degrees.
start	Start angle (radians) of the moving circle's (<i>cmov</i>) centre counterclockwise to the horizontal with the fixed circle's (<i>cfix</i>) centre as the pivot. The tracepoint will start at a peak.

Details

This function scales in either case the radius of the whole cycloid's circumcircle. Thus, for hypocycloids and hypotrochoids it will behave the same way as [zykloid.scaleP](#). For epicycloids and epitrochoids their output will be different. [zykloid.scaleAa](#) scales the outer edge of the figure, while [zykloid.scaleP](#) always scales the circle where the peaks of the figure are located on. In the case of epicycloids and epitrochoids this is at the inside of the figure (see examples).

Figure 1 and 2 show the principle behind cycloid construction:

Value

A dataframe with the columns *x* and *y*. Each row represents a tracepoint position. The positions are ordered along the trace with the last and the first point being identical in order to warrant a closed figure when plotting the data.

zykloid.scaleP

Wrapper for [zykloid](#) which scales a cycloid by the circle its peaks are located on and allows free positioning

Description

While [zykloid](#) provides the basic functionality for calculating cycloids, this functions allows to re-size a cycloid by freely setting the radius of the circle its peaks are located on. In addition, the

cycloid can be re-positioned by locating the fixed circle's midpoint. This function behaves similarly as `zykloid.scaleAa`. See details. See Figures 1, 2, and `zykloid` for the geometrical principles of cycloids.

Usage

```
zykloid.scaleP(A, a, lambda, hypo = TRUE, Cx = 0, Cy = 0,
              RadiusP = 1, steps = 360, start = pi/2)
```

Arguments

A	The Radius of the fix circle before re-sizing. Must be an integer Number > 0. Together with <i>a</i> (see below), <i>A</i> is only determining the cycloid's shape and number of peaks (see <code>npeaks</code>), while its actual size is defined by the argument <i>RadiusP</i> (see below).
a	The radius of the moving circle before re-sizing. Must be an integer Number > 0. Together with <i>A</i> , <i>a</i> only determines the cycloid's shape and number of peaks (see <code>npeaks</code>), while its actual size is defined via the argument <i>RadiusP</i> (see below).
lambda	The distance of the tracepoint from the moving circle's (<i>cmov</i>) centre in relative units of its radius <i>a</i> . <i>lambda</i> = 1 means that the tracepoint is located on <i>cmov</i> 's circumference. For <i>lambda</i> < 1, the tracepoint is on <i>cmov</i> 's area, e.g. if <i>lambda</i> = 0.5, it is halfway between <i>cmov</i> 's centre and its circumference. If <i>lambda</i> > 1 the tracepoint is outside <i>cmov</i> 's area, you might imagine it being attached to a rod which is attached to <i>cmov</i> and crosses its centre. E.g. <i>lambda</i> = 2 would mean that the tracepoint's distance from <i>cmov</i> 's centre equals 2 * <i>a</i> . <i>lambda</i> = 0 produces a circle because the tracepoint is identical with <i>cmov</i> 's centre.
hypo	logical. If TRUE, the resulting figure is a hypocycloid (<i>lambda</i> = 1) or a hypotrochoid (<i>lambda</i> ! = 1), because <i>cmov</i> is rolling along the inner side of the fixed circle (<i>cfix</i>). If FALSE, an epicycloid (<i>lambda</i> = 1) or an epitrochoid (<i>lambda</i> ! = 1) is generated, as <i>cmov</i> is rolling at the outside of <i>cfix</i> 's circumference.
Cx	x-coordinate of the fix circle's midpoint. Default is 0.
Cy	y-coordinate of the fix circle's midpoint. Default is 0.
RadiusP	The actual radius of the circle the cycloid's peaks are located on. Default is 1.
steps	positive integer. The number of steps per circuit of the moving circle (<i>cmov</i>) for which tracepoint positions are calculated. The default, 360, means steps of 1 degree for the movement of <i>cmov</i> . Analogously, steps = 720 would mean steps of 0.5 degrees.
start	Start angle (radians) of the moving circle's (<i>cmov</i>) centre counterclockwise to the horizontal with the fixed circle's (<i>cfix</i>) centre as the pivot. The tracepoint will start at a peak.

Details

This function scales the radius of the circle the cycloids peaks are located on. For hypocycloids and hypotrochoids it will thus behave the same way as `zykloid.scaleAa`. For epicycloids and epitrochoids the output will be different. While `zykloid.scaleAa` scales the outer edge of the figure, `zykloid.scaleP` always scales the circle where the peaks of the figure are located on. In the case of epicycloids and epitrochoids this is at the inside of the figure (see examples below).

Figure 1 and 2 show the principle behind cycloid construction:

Value

A dataframe with the columns x and y . Each row represents a tracepoint position. The positions are ordered along the trace with the last and the first point being identical in order to warrant a closed figure when plotting the data.
